ABSTRACT:- Twenty numbers of farmwomen from each block, thus a total of one hundred numbers of farmwomen were selected randomly from five blocks of Sivasagar district. The farmwomen were selected on the basis of their early experience in keeping local poultry along with Vanaraja chicken at backyard system for the purpose of the study. Items of cost included fixed cost e.g. land and building, equipments and variable costs e.g. cost of day-old chick, feed cost, vaccine cost, medicine cost, labour cost, depreciation on poultry shed and miscellaneous cost. Return items included egg, cocks and spent hens. The labour cost accounted for 58.48 percent of the total cost of production of Vanaraja chicken followed by feed cost (13.58 %), chick cost (12.80 %) and depreciation on poultry house (9.70 %) up to 18 months of age. The total cost of production up to 72 weeks of age was found to be higher in Vanaraja (Rs. 2,577.68) than its local counterpart (Rs. 2,150.98). The maximum amount of income was contributed by selling of eggs (40.00 %) followed by sale of cocks (34.36 %) and sale of spent hens (25.64 %) in case of local chicken. The benefit-cost (B:C) ratio in Vanaraja and local chicken were recorded as 2.60 and 2.27 respectively in the present study. From the study, it can be concluded that small scale Vanaraja rearing is a profitable venture for farmwomen.

Keywords:- B:C ratio, expenditure, local chicken, returns and Vanaraja

I. INTRODUCTION

Poultry keeping is an age old practice among rural and tribal community in Assam. Mostly women and children are involved in village poultry rearing. Most of them rear local poultry at their backyard as secondary source of their livelihood and also to supply family nutrition through production of egg and meat. However, due to inferior productivity of the local chicken some improved dual type chickens like *Vanaraja, Giriraja, Kamrupa* etc. have been gaining popularity among the farmwomen of North-eastern region particularly in Assam. However, no systemic studies have been made so far to know the cost of rearing of such small scale backyard poultry with *Vanaraja* and local chicken. Keeping this point in mind a study has been planned with the following objectives:

1. To know the total cost of production up to 18 months of rearing

- 2. To know the gross income
- 3. To know the net income

4. To know the benefit-cost ratio

II. METHODOLOGY

The study was conducted in *Nazira, Sonari, Sapekhati, Lakwa* and *Demow* development blocks of *Sivasagar* District during the period from January, 2013 to December, 2014. These five blocks were purposively selected as they had higher poultry population as compared with others. Twenty numbers of farmwomen from each block, thus a total of 100 numbers of farmwomen from various self help groups (SHGs) were selected randomly on the basis of their early experience in keeping indigenous as well as *Vanaraja* birds in their household. The farmwomen, who kept a minimum of 10 numbers of indigenous chickens along with 10 numbers of *Vanaraja* chickens of either sex, were considered for the study.

The birds were kept under backyard system. The birds were vaccinated with *Ranikhet* and *Gumboro* disease vaccines as per standard vaccination schedule. The farmwomen were provided with a register to record all the expenses and returns from day old to 18 months of age of the birds. The researcher also helped in doing so and monitored time to time to records all the relevant data in the register. Under backyard system both egg and meat were considered as a source of income and all the produced eggs were considered as table eggs. The eggs and birds were sold to directly to the consumer at the prevailing market rates. Items of cost included fixed cost e.g. land and building, equipments and variable costs e.g. cost of day-old chick, feed cost, vaccine cost, medicine cost, labour cost, miscellaneous cost and depreciation cost. Feed cost was calculated by the following formula:

In case of Vanaraja chicks-

Feed cost= Quantity of broiler starter feed offered up to 28 days of age X Market price of per Kg of

feed

rice

In case of local chicks-

Feed cost= Quantity of broken rice offered up to 28 days of age X Market price of per Kg of broken

Return items included egg, live cocks and spent hens. Data were collected from the selected farmwomen recorded in the register. The net returns were calculated by deducting the returns from eggs or birds from net cost of production. The cost-benefit ratio was calculated by dividing the total gross return by net cost of production. The mortality rates in *Vanaraja* and local chicken were considered as 20 and 10 % respectively during the whole experimental period. The data on various expenses and returns thus collected tabulated and were subjected to statistical analysis as *Snedecor and Cochran (1994)*.

III. RESULTS AND DISCUSSION

The fixed and variable costs for rearing a small unit of backyard poultry of 20 numbers of birds (10 numbers of Vanaraja and 10 numbers of local) are presented in Table 1. The labour cost alone accounted for 70.10 percent of the total cost of production in case of local chicken followed by depreciation on poultry house (11.62 %), chick cost (9.30 %), feed cost (4.65 %) and so on. Similarly in Vanaraja birds also labour cost was the highest (58.48 %) among the cost of production followed by feed cost (13.58 %), chick cost (12.80 %), depreciation cost on poultry house (9.70 %). Uddin et al. (2013) also reported similar result that human labour cost comprised the highest percentage of total cost. In contrast to the present findings, Nath et. al. (2013) reported that feed cost alone contributed 90.95 % of the total cost of production followed by chick cost, medicine cost and vaccine cost in backyard poultry farming in Sikkim. The cost of vaccine only accounted for 1.48 % and 1.23 % of the total cost of production in case of local and Vanaraja chicken respectively. Similarly cost of medicine and feed supplements shared only 2.15 % and 2.84 % of the total cost of production in local and Vanaraja birds respectively. However, Oladunni and Fatuase (2014) reported the cost of medication was only 0.81 % of the total cost in backyard poultry in Nigeria. The lower cost of medicines and other feed supplements in local chicken as compared with Vanaraja chicken might be due to the lesser incidence of disease outbreak in local chicken because of their higher adaptability in backyard system than Vanaraja birds. In the present study, the total cost of production up to 72 weeks of age was found to be higher in Vanaraja (Rs. 2,577.68) than its local counterpart (Rs. 2,150.98). The higher production cost in Vanaraja might be due to higher feed and chick cost. The cost of

*Figures in parenthesis indicates percent of total cost of production

production per bird was estimated as Rs. 215.10 in local and Rs.257.77 in *Vanaraja* chicken. In contrast to the present findings, *Nath et al.* (2013) reported higher cost of production per bird as Rs. 729.50 under scientific backyard rearing of high yielding chicken in Sikkim.

While studying income, it was found that maximum amount of income was contributed by selling of eggs (40.00 %) followed by sale of cocks (34.36 %) and sale of spent hens (25.64 %) in case of local chicken (Table 2). Similar trends of share were also recorded for *Vanaraja* birds under backyard system. *Nath et al.* (2013) also recorded that the highest amount of income in backyard poultry farming was coming from selling of eggs (65.96 %) in Sikkim. The income from *Vanaraja* chicken by selling of eggs was much higher (96.92 %) than its local counterparts, which was due to production of more numbers of eggs by *Vanaraja* birds, might be because of their better genetic makeup. The total gross income in *Vanaraja* chicken was also 37.56 % more

than the local chicken under backyard rearing. Similarly the net income from *Vanaraja* birds was also increased by 51.54 % compared to local chicken. The benefit-cost (B:C) ratio in *Vanaraja* and local chicken were recorded as 2.60 and 2.27 respectively in the present study. The higher benefit cost ratio in *Vanaraja* was due to more egg production and attainment of better body weight in the given period of time as compared to local chicken. *Uddin et al.* (2013) also reported much higher benefit cost ratio (5.57) in native poultry reared in the coastal regions of Bangladesh. However *Das et. al.* (2014) reported much lower benefit cost (B:C) ratio as 1.73 in Rhode Island Red chicken rearing in backyard system in West Bengal. *Nath et al.* (2013) also reported benefit cost ratio as 1.73 in scientific backyard poultry farming in Sikkim. *Sumy et al.* (2010) assessed that there was profitability in rearing indigenous chicken under backyard with a Benefit Cost Ratio of 1.60 and 1.61 in two of the study areas. *Masud and Real* (2013) reported that the average cost benefit ratios of layer and broiler farms were 1.15 and 1.10 respectively under intensive system of management in Bangladesh. The higher B:C ratio in case of *Vanaraja* chicken indicated that *Vanaraja* rearing was much more profitable in the study areas the local chicken.

IV. CONCLUSION

It is revealed that the benefit cost ratio of *Vanaraja* chicken is better than our local chicken under backyard system of rearing, which indicates that small scale *Vanaraja* rearing is a profitable venture for farmwomen. Therefore subsistence poultry keeping could be encouraged in Assam as an effective means for income and employment generation particularly for women which will ultimately reduce the poverty and improve the overall livelihood.

ACKNOWLEDGEMENT

The authors are thankful to the Directorate of Extension Education, Assam Agricultural University, Jorhat-13, Assam for providing facilities and guidance to carry out the research works. The other necessary supports provided by the staffs of Krishi Vigyan Kendra, Sivasagar are also duly acknowledged.
